## Planning and Executing Humanoid Gaits in a World of Stairs

Facoltà di Ingegneria dell'Informazione, Informatica e Statistica  
Corso di Laurea Magistrale in Artificial Intelligence and Robotics

Candidate

Michele Cipriano

ID number 1764645

Thesis Advisor

Prof. Giuseppe Oriolo

Academic Year 2018/2019

Thesis defended on 07 January 2020  
in front of a Board of Examiners composed by:  
Prof. Nome Cognome (chairman)  
Prof. Nome Cognome  
Dr. Nome Cognome

This thesis has been typeset by L<sup>A</sup>T<sub>E</sub>X and the Sapthesis class.

Version: January 5, 2020

Author's email: cipriano.1764645@studenti.uniroma1.it

*Dedicated to  
Donald Knuth*

## Abstract

This document is an example which shows the main features of the  $\text{\LaTeX} 2_{\epsilon}$  class `sapthesis.cls` developed by Francesco Biccari with the help of GuIT (Gruppo Utilizzatori Italiani di  $\text{\TeX}$ ).

## Acknowledgments

*Ho deciso di scrivere i ringraziamenti in italiano per dimostrare la mia gratitudine verso i membri del GuIT, il Gruppo Utilizzatori Italiani di T<sub>E</sub>X, e, in particolare, verso il prof. Enrico Gregorio.*

# Chapter 1

## Introduction

Overview of humanoid robots.

Overview of the thesis (aim, results).

## Chapter 2

# Elevation Map Generation

elevation\_mapping (ROS) [1]

### 2.1 Framework

Todo (overview of elevation\_mapping).

#### 2.1.1 Definitions

Todo (RFs).

#### 2.1.2 Map Update

Todo (range measurements + robot motion).

#### 2.1.3 Map Fusion and Dynamic Environments

Todo.

### 2.2 ASUS Xtion Pro

xtion (RGBD camera)

### 2.3 World of Stairs

(safe zone)

**Figure 2.1.** The ASUS Xtion Pro is equipped with a depth sensor and it is easily configurable to make it work with ROS. This simplifies the integration with `elevation_mapping` and, consequently, the construction of a navigable map.

(a)

(b)

**Figure 2.2.** On the left, NAO humanoid robot with ASUS Xtion Pro placed on top. On the right, NAO humanoid robot in the environment described TODO, right before starting the execution of the experiment.

**Figure 2.3.** RGB image seen by the ASUS Xtion Pro placed on top of the robot. The corresponding depth image is sent to `elevation_mapping` to build the map.

**Figure 2.4.** Elevation map build by `elevation_mapping` for the environment described TODO.

## Chapter 3

# RRT-based Footstep Planning

Considering the *World of Stairs* scenarios discussed previously, the aim of a footstep planner is to determine a feasible sequence of footsteps that allows the humanoid robot to reach a desired goal region  $\mathcal{G}$ , given a representation of the environment, in this case the elevation map described in the previous chapter.

### 3.1 Problem Formulation

Before describing the algorithm, introduced in [2], a more detailed formulation of the problem should be given.

#### 3.1.1 Notation and Plan Feasibility

As introduced before, an elevation map is a proper choice for the representation of the scenarios described by *World of Stairs*, since it is efficient to store and to query. Let's denote the map by  $\mathcal{M}_z$ . The height from the ground of a cell having coordinate  $(x, y)$  is  $z = \mathcal{M}_z(x, y)$ .

Given  $\mathcal{M}_z$ , the goal of the footstep planner (offline) is to find a feasible sequence of footsteps  $\{\mathbf{f}^j\}$  which leads to a desired location  $\mathcal{G}$ , together with the corresponding swing foot trajectories  $\{\mathbf{p}_{\text{swg}}^j\}$ . Let's denote  $\mathbf{f}^j = (x_f^j, y_f^j, z_f^j, \theta_f^j)^T$  as the pose of the  $j$ -th footstep, with  $x_f^j, y_f^j, z_f^j$  position of the footstep and  $\theta_f^j$  yaw orientation of the footstep. Note that in the scenarios represented by *World of Stairs* the roll and pitch angles of the footsteps are always zero.

In order to make the footstep plan feasible, let's introduce the following requirements:

- R1 The height variation between two consecutive footsteps is with a maximum range:  $|z_f^j - z_f^{j-1}| \leq \Delta z_{\text{max}}$ .

- R2 The footstep is fully in contact within the ground, hence, each cell of  $\mathcal{M}_z$  which belongs to the footprint has the same height  $z_f^j$ .
- R3 The swing foot trajectory  $\mathbf{p}_{\text{swg}}^j$  is collision free (apart of course at the start and at the end of the trajectory itself).

Once the footsteps have been generated, they are passed to an online gait generation block (described in Chapter 4) which computes the optimal CoM trajectory  $\mathbf{p}_{\text{CoM}}^*$  that allows the humanoid robot to execute the plan. The optimal swing foot trajectory  $\mathbf{p}_{\text{swg}}^*$  is defined by the appropriate subtrajectory  $\mathbf{p}_{\text{swg}}^j$ .

The reference trajectories  $\mathbf{p}_{\text{swg}}^*, \mathbf{p}_{\text{swg}}^j$  are passed to a pseudoinverse-based kinematic controller to compute joint commands  $\dot{\mathbf{q}}$  for the robot. Proprioceptive feedback is used for both gait generator block and kinematic controller.

## 3.2 Algorithm

The following algorithm [2], which is based on RRT (Rapidly Exploring Random Tree), finds a feasible sequence of footsteps in a *World of Stairs* scenario given the elevation map  $\mathcal{M}_z$  of the environment, the goal region  $\mathcal{G}$  and the starting configuration of the feet  $\mathbf{f}_L, \mathbf{f}_R$ . The generated sequence connects the starting point to the goal.

### 3.2.1 Pseudocode

The footstep planner, whose behaviour is described by Algorithm 1 iteratively builds a tree  $\mathcal{T}$  of feet configurations in a randomized way. In general, a vertex  $v = (\mathbf{f}_{\text{sup}}, \mathbf{f}_{\text{swg}})$  specifies the pose of the support foot and the swing foot during the phase of double support. An edge connecting two vertices exists when there exists a collision free trajectory of the swing foot between the two configurations.

The algorithm starts by initializing the tree with the initial configuration of the left and the right foot (line 1). At each iteration, a point  $\mathbf{p}_{\text{rand}}$  is selected randomly on the ground (line 5). Here, the planner randomly choose between exploration and exploitation mode. In the first case  $\mathbf{p}_{\text{rand}}$  is generated by randomly selecting a pair of coordinates  $x, y$  and retrieving the  $z$  corrdinate from the elevation map  $\mathcal{M}_z$ . In the second case  $\mathbf{p}_{\text{rand}}$  is sampled from  $\mathcal{G}$ . At this point, the vertex  $v_{\text{near}}$  of  $\mathcal{T}$  that is closest to  $\mathbf{p}_{\text{rand}}$  is selected (line 6) in order to check whether it can be connected to the tree  $\mathcal{T}$ . The distance between  $v_{\text{near}}$  and  $\mathbf{p}_{\text{rand}}$  is determined using the following metric:

$$\gamma(v, \mathbf{p}) = d(\mathbf{m}, \mathbf{p}) + \alpha|\theta_p| \quad (3.1)$$

where  $d(\mathbf{m}, \mathbf{p})$  is the Euclidean distance between the midpoint  $\mathbf{m}$  between the feet (hence, between  $\mathbf{f}_{\text{sup}}$  and  $\mathbf{f}_{\text{swg}}$  in  $v$ ) and  $\mathbf{p}$ ,  $\theta_p$  is the angle between the robot sagittal

axis and the line joining  $\mathbf{m}$  to  $\mathbf{p}$ , and  $\alpha > 0$ . Once  $v_{\text{near}}$  has been selected, the foot poses  $\mathbf{f}_{\text{sup}}^{\text{near}}, \mathbf{f}_{\text{swg}}^{\text{near}}$  are extracted from it. A candidate footstep  $\mathbf{f}^{\text{cand}}$  is randomly generated (line 7) by selecting a final pose of the swing foot from the catalogue of primitives  $U$  defined with respect to  $\mathbf{f}_{\text{sup}}^{\text{near}}$ , as shown in Fig. 3.1 and defined in the next section. As before, the  $z$  coordinate of  $\mathbf{f}^{\text{cand}}$  is determined by  $\mathcal{M}_z$ . On line 8, requirements R1-R2 defined above are checked for  $\mathbf{f}^{\text{cand}}$ . In positive case, a collision checking algorithm (lines 9-13) is performed to verify whether there exists a collision free trajectory  $\mathbf{p}_{\text{swg}}^{\text{cand}}$  (a second degree polynomial equation) that brings the swing foot from  $\mathbf{f}_{\text{swg}}^{\text{near}}$  to  $\mathbf{f}^{\text{cand}}$ . In positive case, also requirement R3 is verified and a new vertex  $v_{\text{new}} = (\mathbf{f}^{\text{cand}}, \mathbf{f}_{\text{sup}}^{\text{near}})$  is added to the tree  $\mathcal{T}$  as a child of  $v_{\text{near}}$  (lines 14-17). The algorithm terminates when the midpoint  $\mathbf{m}$  between the feet at the new vertex  $v_{\text{new}}$  is inside the goal region  $\mathcal{G}$  or a maximum number of iterations  $i_{\text{max}}$  has been reached (line 18). When a solution has been found, the path joining the initial vertex  $(\mathbf{f}_L, \mathbf{f}_R)$  to  $v_{\text{new}}$  is extracted from the tree and the footstep sequence  $\{\mathbf{f}^j\}$  is reconstructed together with the swing foot trajectories  $\{\mathbf{p}_{\text{swg}}^j\}$ .

17      compute midpoint  $\mathbf{m}$  between the feet at  $v_{\text{new}}$ ;
18 until  $\mathbf{m} \in \mathcal{G}$  or  $i = i_{\text{max}}$ ;

```

---

### 3.3 Implementation

The planner has been implemented in C++ and it has been tested on both dynamic environments and NAO humanoid robot. The elevation map is either generated by the `elevation_mapping` framework or manually generated before the execution of the program. Experiments are described in detail in Chapter 5. Note that to simplify the communication between `elevation_mapping` and the planner and the communication between the planner and the robot, the planner has been executed on an external computer, which is connected to the robot through an ethernet cable. The plan is sent through TCP. The communication is designed with the idea to extend the planner in order to handle replanning phases and dynamic environments.

5

#### 3.3.1 Catalogue of Primitives

As mentioned before, the catalogue of primitives specifies the possible footsteps that the robot can perform at each step. In this thesis the catalogue for the NAO humanoid robot (left foot with respect to right foot) has been defined as:

$$(x, y, \theta) \in \{-6.0, 0.0, 6.0, 8.0, 10.0\} \times \{13.0, 14.0\} \times \{0, \pi/12\} \quad (3.2)$$

The catalogue of primitives of the right foot with respect the left foot is symmetric and it is shown in Fig. 3.1. The footstep planning hyperparameters have been set in the following way: the goal region has been defined as a circle of radius 0.01m,  $\alpha = 1$ ,  $\Delta z_{max} = 0.045\text{m}$ ,  $h_{min} = 0.02\text{m}$ ,  $h_{max} = 0.07\text{m}$ ,  $\Delta h = 0.01\text{m}$ . The resolution of  $\mathcal{M}_z$  has been set to 0.01m when using maps generated by `elevation_mapping` and to 0.02m when using maps generated manually.

**Figure 3.1.** The catalogue of primitives (blue color) specifies the possible poses of the candidate footstep  $\mathbf{f}^{\text{cand}}$  with respect to the pose of the current support foot  $\mathbf{f}_{\text{sup}}^{\text{near}}$ . The figure shows the case where the left foot is the support foot. The catalogue for the case where the right foot is the support foot is specular. The  $z$  coordinate of a candidate footstep can be retrieved directly from the elevation map  $\mathcal{M}_z$ .

## Chapter 4

# Variable Height CoM IS-MPC

Before describing in detail the model [3] that allows humanoid robots to walk on uneven terrain (in this case *World of Stairs*), it is important to introduce the notation and to make an overview of the previous works. Differently from manipulators, which are fixed to the ground, humanoids need to maintain equilibrium while walking. The contact with the ground is, in fact, continuously changed due to walking itself. Usually, this is achieved by making sure that the ZMP (Zero Moment Point) is always within the convex hull of the support polygon. The ZMP, introduced in [4], is the point where the horizontal component of the moment of the ground reaction forces becomes zero. To generate this kind of motion, usually a simplified model which only considers the CoM (center of mass) of the robot is used. In particular, by neglecting the robot angular momentum and by assuming the CoM height is constant, the CoM dynamics can be treated as a LIP (Linear Inverted Pendulum), introduced for the first time in [5]. The Linear Inverted Pendulum model easily allows to design control schemes for the generation of the CoM reference trajectory, like the Preview Control [6] and the Model Predictive Control [7]. Before discussing the LIP and extending it to the Variable Length Inverted Pendulum, let's discuss the 3D motion model of the CoM reminding that the CoP (Center of Pressure) in case of flat ground is the point of application of the ground reaction force.

### 4.1 3D Motion Model

Let  $(x_z, y_z, z_z)$  and  $(x_c, y_c, z_c)$  respectively be the position of the ZMP and the position of the CoM. Assuming that the humanoid robot is walking on flat ground (hence the gravity acceleration components on  $x$  and  $y$  are zero) and neglecting the angular momentum around the CoM, the ZMP can be anywhere along the line connecting the CoP (located on the piece of surface upon which the support foot is

**Figure 4.1.** When walking on flat ground, or more in general on piecewise-horizontal ground as in the figure, the ZMP can be anywhere between the line connecting the CoP and the CoM.

placed) and the CoM (Fig. 4.1), it is possible [8] to obtain the dynamics of the CoM:

$$\ddot{x}_c = \frac{\ddot{z}_c + g}{z_c - z_z}(x_c - x_z) \quad (4.1)$$

$$\ddot{y}_c = \frac{\ddot{z}_c + g}{z_c - z_z}(y_c - y_z) \quad (4.2)$$

$$\ddot{z}_c = \frac{f_z}{m} - g \quad (4.3)$$

where  $g$  is the gravity acceleration,  $f_z$  is the z-component of the ground reaction force, acting as an external input, and  $m$  is the total mass of the humanoid robot. The condition for maintaining equilibrium is that CoP is internal to the support polygon. Since the CoP, the CoM and the ZMP are colinear, as shown in Fig. 4.2, the condition is equivalent to the ZMP being internal to the polyhedral cone having CoM as vertex and support polygon as cross-section.

## 4.2 LIP

The above motion model is nonlinear and difficult to use for gait generation. Usually, to make the model linear, it is assumed that the ground is horizontal and the CoM has constant elevation with respect to the ground (i.e.  $z_c = \bar{z}_c$ ). As a consequence,

**Figure 4.2.** The CoP should be internal to the support polygon, which is equivalent to the ZMP being internal to the polyhedral cone with the CoM as a vertex.

it is possible to set  $z_z = 0$  making the CoP and the ZMP coincident, hence obtaining the LIP model:

$$\ddot{x}_c = \omega_0^2(x_c - x_z) \quad (4.4)$$

$$\ddot{y}_c = \omega_0^2(y_c - y_z) \quad (4.5)$$

where  $\omega_0^2 = g/\bar{z}_c$ . This linear model, however, is not suitable for gait generation over uneven terrain.

### 4.3 Variable Height CoM Motion Model

Requiring the CoM to move at a constant height is not the only way to make the system linear. A more general way is to constraint its vertical motion such that:

$$\frac{\ddot{z}_c + g}{z_c - z_z} = \omega^2 \quad (4.6)$$

with  $\omega$  arbitrary constant.

Using the above equation, the CoM dynamics become:

$$\ddot{x}_c = \omega^2(x_c - x_z) \quad (4.7)$$

$$\ddot{y}_c = \omega^2(y_c - y_z) \quad (4.8)$$

$$\ddot{z}_c = \omega^2(z_c - z_z) - g \quad (4.9)$$

The above equations are linear and have a LIP-like structure with the ZMP coordinates  $(x_z, y_z, z_z)$  acting as control inputs. This 3D model, against the model of the LIP described in Eqs. (4.4-4.5), allows vertical motion of the CoM, thus, it can be used for gait generation on uneven terrain, considering the balance condition described by Fig. 4.2.

## 4.4 MPC Formulation

Before describing an MPC scheme for gait generation based on the above equations, it is important to notice that all of them include an unstable subsystem. For example, let's consider Eq. (4.7). It is possible to decompose the system into a stable and an unstable subsystem by performing the following change of coordinates:

$$x_s = x_c - \dot{x}_c/\omega \quad (4.10)$$

$$x_u = x_c + \dot{x}_c/\omega \quad (4.11)$$

The dynamics of  $x_u$  is:

$$\dot{x}_u = \dot{x}_c + \omega(x_c - x_z) \quad (4.12)$$

which is unstable. It is however possible to prove [9] that  $x_u$ , and consequently  $x_c$ , will not diverge if a certain initial condition is satisfied (discussed in section 4.4.2). The same reasoning applies for the other two variables.

Let's perform a dynamic extension and choose the control variable as the ZMP velocities  $\dot{x}_z, \dot{y}_z, \dot{z}_z$  rather than the ZMP itself. On the  $x$  axis, the motion model becomes:

$$\begin{pmatrix} \dot{x}_c \\ \ddot{x}_c \\ \dot{x}_z \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 \\ \omega^2 & 0 & -\omega^2 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} x_c \\ \dot{x}_c \\ x_z \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \dot{x}_z \quad (4.13)$$

The same applies for the other two axes with an additive term  $g$  appearing in the second equation of the dynamics along the  $z$  axis.

Let's consider piecewise-constant control inputs over sampling intervals of duration  $\delta$ , with a prediction horizon  $T_h = N \cdot \delta$ . Let's denote the current time instant by  $t_k$  and successive instants within prediction horizon  $t_{k+i}, i = 1, \dots, N$  by  $t_{k+i}$ . At a generic instant  $t_j$ :

$$\dot{x}_z(t) = \dot{x}_z^j, \quad t \in [t_j, t_{j+1}) \quad (4.14)$$

hence, the ZMP position along the  $x$  axis in the time interval  $[t_j, t_{j+1}]$  is:

$$x_z(t) = x_z^j + (t - t_j)\dot{x}_z^j, \quad t \in [t_j, t_{j+1}] \quad (4.15)$$

### 4.4.1 ZMP constraints

Before describing the ZMP constraints in the 3D case (Fig. 4.2), let's discuss the 2D case.

When walking on fully horizontal ground, the robot keeps the equilibrium if the ZMP remains inside the support polygon. Let's denote by  $(x_f^j, y_f^j, \theta_f^j)$  the pose of the generic footstep within the given sequence. Let's use a fixed-shape moving ZMP constraint [10] to enforce balance. The admissible region for ZMP at  $t_{k+i}$  is centered

**Figure 4.3.** The ZMP constraint moves from a support foot to the following one during double support phase.

in  $(x_f^{k+i}, y_f^{k+i})$  and has orientation  $\theta_f^{k+i}$ . In single support case,  $(x_f^{k+i}, y_f^{k+i}, \theta_f^{k+i})$  coincide with the pose of the support foot, hence,  $(x_f^j, y_f^j, \theta_f^j)$ . In double support case,  $(x_f^{k+i}, y_f^{k+i}, \theta_f^{k+i})$  gradually slide from the position and orientation of the previous support foot to those of the next, as shown in Fig. 4.3. The expression of the ZMP constraint in 2D can be written as:

$$-\frac{1}{2} \begin{pmatrix} d_x^z \\ d_y^z \end{pmatrix} \leq R_{k+i}^T \begin{pmatrix} x_z^{k+i} - x_f^{k+i} \\ y_z^{k+i} - y_f^{k+i} \end{pmatrix} \leq \frac{1}{2} \begin{pmatrix} d_x^z \\ d_y^z \end{pmatrix} \quad (4.16)$$

where  $d_x^z$  and  $d_y^z$  are the width and the height of the rectangular constraint region and  $R_{k+i}^T$  is the rotation matrix associated to the orientation  $\theta_f^{k+i}$ . Note that  $(x_z^{k+i}, y_z^{k+i})$  is the predicted position of the ZMP, which can be expressed as a linear combination of the control variables:

$$x_z^{k+i} = x_z^k + \delta \sum_{j=0}^{i-1} \dot{x}_z^{k+j} \quad (4.17)$$

Eq. (4.16) must be imposed for  $i = 1, \dots, N$ .

In the 3D case, the ZMP is allowed to leave the ground in order to generate CoM motions along the  $z$  axis as well. As previously discussed, balance condition requires ZMP to remain inside polyhedral cone defined by the support polygon and CoM (Fig. 4.2). When ZMP is allowed to move vertically, the constraint becomes nonlinear. In order to remove nonlinearity it is possible to consider a subregion of

**Figure 4.4.** The polyhedral cone representing the ZMP constraint and the box used to approximate the constraint (which becomes linear).

the polyhedral cone, for example a box constraint, as shown in Fig. 4.4:

$$-\frac{1}{2} \begin{pmatrix} \tilde{d}_x^z \\ \tilde{d}_y^z \\ d_z^z \end{pmatrix} \leq R_{k+i}^T \begin{pmatrix} x_z^{k+i} - x_f^{k+i} \\ y_z^{k+i} - y_f^{k+i} \\ z_z^{k+i} - y_f^{k+i} \end{pmatrix} \leq \frac{1}{2} \begin{pmatrix} \tilde{d}_x^z \\ \tilde{d}_y^z \\ d_z^z \end{pmatrix} \quad (4.18)$$

where  $d_z^z$  defines the maximum allowed vertical ZMP displacement with respect to the ground. To guarantee that the box is contained in the cone, its  $x$  and  $y$  dimensions are respectively reduced to  $\tilde{d}_x^z, \tilde{d}_y^z$ :

$$\tilde{d}_x^z = d_x^z \left( 1 - \frac{d_z^z}{2z_c^{\min}} \right) - \frac{d_z^z}{z_c^{\min}} \Delta x_c \quad (4.19)$$

where  $\Delta x_c$  is the maximum expected displacement of the CoM with respect to the center of the support foot and  $z_c^{\min}$  is the minimum expected value for CoM height. The same reasoning applies for  $\tilde{d}_y^z$ . Similarly to the 2D case, the box constraint is kept fixed during single support, while during double support the box slides linearly from its position around the previous support foot to its position around the next support foot, thus, always remaining within the polyhedral cone which defines the ZMP balance constraint, as shown in Fig. 4.5.

#### 4.4.2 Stability constraint

As previously seen, the motion model (4.7-4.9) is unstable, hence, it is not guaranteed that the CoM position is bounded with respect to the ZMP in general. This could

**Figure 4.5.** The ZMP box constraint moves from a support foot to the following one during double support phase.

make the generated gait unrealizable. However, as mentioned before and as discussed in [9, 11], it is possible to prove that if the initial condition  $(x_c^k, \dot{x}_c^k)$  satisfies:

$$x_c^k + \frac{\dot{x}_c^k}{\omega} = \omega \int_{t_k}^{\infty} e^{-\omega(\tau-t_k)} x_z(\tau) d\tau \quad (4.20)$$

then  $x_c$  remains bounded with respect to  $x_z$  for all  $t$ . An analogous condition can be given for  $y_c$  dynamics. Regarding  $z_c$ , it is possible to prove its boundedness by using the following initial condition:

$$z_c^k + \frac{\dot{z}_c^k}{\omega} = \frac{g}{\omega^2} + \omega \int_{t_k}^{\infty} e^{-\omega(\tau-t_k)} z_z(\tau) d\tau \quad (4.21)$$

The above stability conditions can be enforced in the MPC formulation by writing them with respect to the control variables  $\dot{x}_z^{k+i}, \dot{y}_z^{k+i}, \dot{z}_z^{k+i}$ . For  $x_c$ , and similarly for  $y_c$ , the initial condition can be writtes as:

$$\frac{1}{\omega} \frac{1 - e^{-\delta\omega}}{1 - e^{-N\delta\omega}} \sum_{i=0}^{N-1} e^{-i\delta\omega} \dot{x}_z^{k+i} = x_c^k + \frac{\dot{x}_c^k}{\omega} - x_z^k \quad (4.22)$$

which can be obtained from (4.20) by considering that the ZMP trajectory (4.17) is piecewise linear and that the contribution beyond the prediction horizon is computed assuming infinite replication of the control variables within the prediction horizon

itself. A similar initial condition can be written for  $z_c$  starting from (4.21), where  $\dot{z}_z$  is set to zero beyond the prediction horizon (truncated tail):

$$\frac{1 - e^{-\delta\omega}}{1 - e^{-N\delta\omega}} \sum_{i=0}^{N-1} e^{-i\delta\omega} \dot{z}_z^{k+i} = z_c^k + \frac{\dot{z}_c^k}{\omega} - z_z^k - \frac{g}{\omega^2} \quad (4.23)$$

A more detailed discussion can be found in [12].

## 4.5 MPC Algorithm

Now that the constraints have been expressed with respect to the input variables, it is possible to define the MPC scheme used to generate the gait. In particular, the MPC algorithm solves a QP problem at each iteration determining the trajectory of the CoM. Note that the footsteps are assigned in advance.

Considering the decision variable vectors:

$$\dot{X}_z^k = (\dot{x}_z^k, \dots, \dot{x}_z^{k+N-1})^T \quad (4.24)$$

$$\dot{Y}_z^k = (\dot{y}_z^k, \dots, \dot{y}_z^{k+N-1})^T \quad (4.25)$$

$$\dot{Z}_z^k = (\dot{z}_z^k, \dots, \dot{z}_z^{k+N-1})^T \quad (4.26)$$

the QP problem can be defined as:

$$\begin{aligned} \min_{\dot{X}_z^k, \dot{Y}_z^k, \dot{Z}_z^k} \sum_{i=1}^N & \left[ (\dot{x}_z^{k+i})^2 + (\dot{y}_z^{k+i})^2 + (\dot{z}_z^{k+i})^2 + \right. \\ & \left. \beta \left( (x_z^{k+i} - x_f^{k+i})^2 + (y_z^{k+i} - y_f^{k+i})^2 + (z_z^{k+i} - z_f^{k+i})^2 \right) \right] \\ \text{s.t. } & \text{ZMP constraint (4.18)} \\ & \text{stability constraints (4.22), (4.23)} \end{aligned}$$

where the cost function includes the decision variables for regularization purposes and a term which attempts to bring the ZMP to the center of the footstep.

Each MPC iteration starts at  $t_k$  and executes the steps described in Algorithm 2, defining the trajectory of the CoM.

---

### Algorithm 2: MPC iteration

---

**Result:** CoM trajectory

---

- 1 Compute  $\dot{X}_z^k, \dot{Y}_z^k, \dot{Z}_z^k$  that solve the QP problem;
  - 2 From the solutions, extract the first control samples  $\dot{x}_z^k, \dot{y}_z^k, \dot{z}_z^k$ ;
  - 3 Set  $\dot{x}_z = \dot{x}_z^k$  in (4.13) and integrate from  $(x_c^k, \dot{x}_c^k, x_z^k)$  to obtain  $x_c(t), \dot{x}_c(t), x_z(t)$  for  $t \in [t_k, t_{k+1}]$ . The same applies for  $y, z$ .
-

## 4.6 BHuman implementation

The MPC scheme has been implemented in C++ upon the BHuman framework [13] and it has been tested on both dynamic environments and NAO humanoid robot. The QP problem has been solved using qpOASES [14]. The footstep plan is either generated by the footstep planner described in Chapter 3 or manually assigned before the execution of the program. Experiments are described in detail in Chapter 5. Note that to speed up the execution of the code in order to keep computation within the sampling time of the kinematic controller, the rotation matrix of the ZMP constraint described in Eq. (4.18) has been neglected. This does not create any problem if the size of the box is small enough to stay within the polyhedral cone regardless of the rotation of the feet. The MPC hyperparameters have been set in the following way:  $\omega = 6.68\text{s}^{-1}$ , the step duration  $T_s = 0.48\text{s}$  of which  $t_{\text{SS}} = 0.30\text{s}$  of single support and  $t_{\text{DS}} = 0.18\text{s}$  of double support. The size of the box constraint have been set to  $\tilde{d}_x^z = 0.05\text{m}$ ,  $\tilde{d}_y^z = 0.05\text{m}$ ,  $\tilde{d}_z^z = 0.05\text{m}$ .

## Chapter 5

# Experiments

### 5.1 NAO

Brief description of NAO v5 (which is running BHuman).

### 5.2 Stair climbing

Stair climbing (unknown environment).

### 5.3 Obstacle avoidance

Obstacle avoidance (unknown environment).

## Chapter 6

# Conclusion

What's next: tracker -> makes it possible to continuously build the map with elevation\_mapping -> replanning -> makes it possible to move in whatever environment (World of Stairs).

Rough environments?

## Chapter 7

# Style features of `sapthesis`

In this chapter I will discuss my stylistic choices of `sapthesis`. I will show the page layout geometry and I will describe the page style.

### 7.1 Page layout

The page is fixed at the dimensions of an A4 paper, therefore you have to print your thesis on A4 paper to obtain the best results. The font dimension is fixed at 11 pt. The text column and the margins are chosen to fill to the best an A4 paper while keeping a reasonable line length (396 pt) for a good readability. The text height and the text width are in golden ratio ( $\sim 1.6180$ ) as well as the outer and inner margins in a two-side document after binding margin removal. Also the top margin (excluding the header) and bottom margin are in the golden ratio. In Fig. 7.1 a sketch of the `sapthesis` page layout is shown.

### 7.2 Page style

The captions have a smaller font respect to the text and the label is in boldface. The appearance of the margin notes has been improved. They have the same font dimension of the footnotes and are typed in italics. Moreover I defined a new command to typeset margin note aligned to the left on the right page and vice versa on the left page. Notice that if a binding margin greater than 1.5 cm is used, the dimensions of the margin notes become too small and very ugly. Do not use them in this case.

The mathematical objects, figures and tables are numbered within the chapters (e.g. 1.1, 1.2, ... for the first chapter, 2.1, 2.2 for the second one and so on. ...). See

**Figure 7.1.** Page layout scheme of `sapthesis` class using a zero binding margin.

**Table 7.1.** This is a simple table.

Letter	Test	Test
A	C	E
B	D	F

for example the number of this simple equation

$$x_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \quad (7.1)$$

The title page is automatically composed when the `\maketitle` command is given. The parameters needed for the title page, author, title, etc..., are supplied by dedicated commands explained in the next section. Two copies of the university logo in `pdf` format, one for color printing and the other one for black and white printing, are supplied in the `sapthesis` package. They are shown in Fig. 7.2.

### 7.3 About figures and tables

As regards the image formats, please use vector images as much as possible! Use `jpg` images only for photographs! `pdfLATEX` supports the `pdf`, `jpg` and `png` formats.

A very simple table is show in Tab. 7.1. Remember to typeset always the table caption above the table. Do not use vertical lines.

Figure 7.2. Logo of the Sapienza – University of Rome.

## Appendix A

# Special commands provided by sapthesis

Sapthesis provides some special commands, particularly useful for scientific works. You can use for example the roman shape, instead of the italic, for the imaginary unit (`\iu`) and Napier's number (`\eu`):

$$e^{i\pi} + 1 = 0 \quad (\text{A.1})$$

There are also two commands to speed up the writing of derivatives. In the following example we have used the commands `\der` and `\pder`:

$$\frac{\partial f}{\partial x} \quad \frac{\partial^2 f}{\partial y^2} \quad (\text{A.2})$$

Sapthesis provides also 4 commands to improve the writing of subscripts, `\rb` and `\tb`, and superscripts, `\rp` and `\tp`. Two of these commands, `\rb` and `\rp`, can be used both in text and in math mode and compose their argument in roman. The other two, `\tb` and `\tp`, can be used only in text mode and compose their argument as are. Here it is an usage example of `\rb` and `\rp`:

$$a_b \neq a_{\text{b}} \quad a^b \neq a^{\text{b}}$$

And here it is an usage example of `\tb`: *Cu<sub>It</sub>* indicates copper bought in Italy. And a usage example of `\ts`: *Cher G<sup>le</sup> Napoléon*.

Then several commands for the correct typesetting of unit of measurements are provided. For example the command `\un` typesets its argument in roman and leaves a thin space between the number and the unit: 25 m, 3.5 m/s. Other commands are: (`\g`) 45°, (`\C`) 30 °C, (`\A`) 12 Å, (`\micro`) 40 μm, (`\ohm`) 27 Ω.

We have also `\x` as abbreviation of `\times`: `\$7 \x 10^5\$` gives  $7 \times 10^5$ . Then `\di` is the differential symbol which automatically insert the correct spacing.

$$\int x \, dx$$

Finally we have defined the color `sapred` which is the official color of Sapienza – University of Rome. It is defined as RGB(130,36,51). `This text is written with the color sapred.`

In the following dummy text you can observe the usage of `\mnote` command which typesets fancy margin notes.

Lorem ipsum dolor sit amet, consectetur adipiscing elit. Ut purus elit, vestibulum ut, placerat ac, adipiscing vitae, felis. Curabitur dictum gravida mauris. Nam arcu libero, nonummy eget, consectetur id, vulputate a, magna. Donec vehicula augue eu neque. Pellentesque habitant morbi tristique senectus et netus et malesuada fames ac turpis egestas. Mauris ut leo. Cras viverra metus rhoncus sem. Nulla et lectus vestibulum urna fringilla ultrices. Phasellus eu tellus sit amet tortor gravida placerat. Integer sapien est, iaculis in, pretium quis, viverra ac, nunc. Praesent eget sem vel leo ultrices bibendum. Aenean faucibus. Morbi dolor nulla, malesuada eu, pulvinar at, mollis ac, nulla. Curabitur auctor semper nulla. Donec varius orci eget risus. Duis nibh mi, congue eu, accumsan eleifend, sagittis quis, diam. Duis eget orci sit amet orci dignissim rutrum.
